

Abducadir Aligure

Learning by doing.

I'm Abducadir, a Purchasing and Logistics Engineering student in Helsinki, with only my bachelor's thesis left. I'm looking for an entry-level role at a startup where I can contribute, take responsibility and learn from the people around me.

I bring over five years of customer-facing experience and a year and a half of building software with AI. These projects show how I approach a problem, what I've tried and what I've learned along the way.

PEOPLE

Listen, explain and follow through.

OPERATIONS

Learn how everyday tasks fit together.

BUILDING

Try an idea, check it and improve it.

Helsinki, Finland | Finnish · English · Somali

START HERE

Selected work

Five projects, from customer work to software MVPs. Each started with a problem I wanted to understand better.

PROJECT	FOCUS	STAGE
AQOON	Services and operations	Live service platform
AQOON Letter Assistant	AI and language	Implemented MVP
SafkaStock	Logistics and operations	Piloted, now paused
RideLink	Coordination and operations	Implemented MVP
DM Order Organizer	AI and operations	Implemented MVP

Other work

A few smaller projects I worked on for practice, coursework or curiosity.

How I work

I use Codex and Claude Code daily to help me build and work through code. Each project gave me a chance to try something, check how it worked and decide what to improve next.

SERVICES AND OPERATIONS

AQOON

The gap between a service being available and a family being able to use it.

Live service platform | Community research, client outreach, service delivery and development

The problem

I kept seeing two sides of the same problem. Institutions had programmes with places to fill, while Somali families who could benefit from them often did not know they existed. In conversations with families, I found that the barrier could be language, trust, an unfamiliar application or simply not knowing whom to ask.

What I did

I spent several weeks speaking with families, then approached institutions with an offer to help bridge that gap. The work means reaching people in their own language, listening to what is blocking them, helping with enrolment and following up. I also built the AQOON website, enquiry forms and a private tracker with Claude Code to support that work.

How the tools help

The tracker keeps requests, conversation notes and next actions together, so I can see what still needs attention. I separated initial contact, application progress and a confirmed service start. That helps me follow up on what a family actually needs next, instead of treating every enquiry as a completed outcome.

What came from it

First client project (a national private daycare chain) delivered and paid 2026, second project agreed with a city hobby program in Uusimaa.

What I learned

I learned that explaining a service is often only the first step. Someone may understand it and still need help with a form or a conversation before they can move forward. Doing the work myself helped me decide which parts needed a tool and which parts needed a person to stay in touch.

Built with: HTML, CSS and JavaScript / Supabase / Vercel

The service website and its source are public. The enquiry and follow-up tools are used privately.

AI AND LANGUAGE

AQOON Letter Assistant

Helping someone understand a letter, beyond translating its words.

Implemented MVP | Problem research, application design and AI-assisted development

The problem

Growing up, I helped my family understand Finnish official letters. Even after translating the words, there could still be questions: what does this mean for me, do I need to reply, and is there a date I need to remember? I wanted to explore whether AI could make those letters easier to understand in plain Somali.

What I built

I built an application that explains a letter and supports follow-up questions and reply drafts. Using Claude Code, I developed the screens and the steps around the AI: a rule-based classifier sorts messages into seven types, the app chooses a model, and checks run on the response before it is shown.

A problem inside the problem

An explanation becomes less useful if it adds a date or commitment that was never in the letter. I worked on checks for invented dates, mismatched weekdays and unsupported promises in reply drafts. This taught me to think about the kind of message being handled and the information the user has actually provided.

Where I got to

The core MVP is implemented, including the classifier, model routing and tests for the response checks. My next step would be to try a wider range of letters with Somali-speaking readers and find out which explanations help them understand what to do next.

What I learned

A fluent answer is easy to mistake for a useful one. I learned to spend more time on the source information, the checks around the model and how the explanation reads to the person who needs it. I want to keep getting better at testing those parts together.

Built with: Next.js and React / Express and Supabase / LLM APIs and model routing

A separate application within AQOON. The source is private.

LOGISTICS AND OPERATIONS

SafkaStock

A shop-owner conversation about margins, buying decisions and food going bad.

Piloted, now paused | Co-development, invoice imports, stock and sales tools, customer testing

The conversation that started it

I asked a shop owner about his margins, and he could not tell me. When I asked how he decided what to buy, he said he went to the market and bought what was cheapest. He also could not say what was likely to go bad that day. That stayed with me. He was making everyday buying decisions without a clear view of his margins or what needed using first.

The problem I wanted to solve

Small food businesses can have supplier invoices and sales data in a point-of-sale system, yet still struggle to connect them to the stock on the shelf. I wanted to bring purchases, sales, stock counts and waste into one place, so an owner could start understanding costs and stock movement before deciding what to buy next.

What we built, and my part

A friend and I built SafkaStock as a restaurant stock-management MVP. I worked on stocktake and sales-entry screens, backend endpoints and importing purchase information from invoices. That included PDF parsing, AI-assisted extraction and matching invoice items to products already in the system. We developed the product across several iterations, building on my friend's foundation.

What happened

During my 135-hour internship with the Witas Agile Experiments Incubator in October and November 2025, I worked on the MVP and tested it with customers. We reached a pilot, but I spent too much time expanding the product before checking whether people would keep using it. The project was paused in summer 2026.

What I learned

The shop-owner conversation gave me a reason to investigate, but it did not tell me which solution people would use. I would now choose one decision to help with, test a smaller version earlier and watch whether it becomes part of someone's routine. This project taught me that understanding a problem and finding demand for a product are separate pieces of work.

Built with: React / Express / Prisma and PostgreSQL / Invoice extraction

Co-built with a friend, starting from their foundation. The source is private.

COORDINATION AND OPERATIONS

RideLink

One shared event for organising lifts to a match.

Implemented MVP | Application design and AI-assisted development

The problem

Arranging lifts to a youth sports match means keeping track of drivers, spare seats and people who still need a ride. I wanted to put those details around the event itself, so parents could see the options and join from one shared link.

What I built

I built a manager dashboard, calendar imports and a parent-facing page for offering or claiming seats. Managers sign in to organise events. Parents can use the event link without creating an account, which removes a step from a task that should be quick.

Working through the details

If two people try to claim the last seat at the same time, the screen alone cannot decide who gets it. I implemented a database transaction that checks remaining capacity before saving a booking. Working through that helped me understand why a simple-looking feature still needs careful handling behind the scenes.

Where I got to

The core MVP is implemented, from importing an event to sharing it and booking a seat. Keeping imported events up to date still needs work, including handling cancellations. I would finish that before testing the full routine with a team.

What I learned

I learned to think beyond the first successful booking. Events change and people act at the same time. Considering those situations changed how I designed both the booking process and the information parents need to see.

Built with: Next.js, React and TypeScript / Supabase / iCalendar imports

Implemented MVP with private source.

AI AND OPERATIONS

DM Order Organizer

Keeping track of an order after the conversation moves on.

Implemented MVP | Application design, AI-assisted development and onboarding

The problem

A customer can place an order through a conversation, with the details spread across several messages. The seller then has to pull those details together and remember what has been paid for or sent. I wanted to try a small tool that helps sellers turn those messages into orders they can find and follow up on.

What I built

The seller pastes the messages, and AI suggests an order draft. They can check and edit it before saving, then mark the order as paid or sent. I built that flow along with search, filters and CSV export, and worked on the order of the fields and the first-use guidance.

The choice that mattered

I kept reviewing and saving as separate steps. A draft can be missing something or misunderstand a message, so the seller needs a clear chance to correct it. I started with pasted text to work on this core task before considering connections to messaging platforms.

Where I got to

The core MVP is implemented, from pasted messages to an editable draft and a saved order. The next thing I would test is how well it handles a seller's own conversations: what needs correcting, what is missing and whether the review actually saves them effort.

What I learned

The AI extraction is only part of the task. I also had to think about how someone checks the draft and finds the order again later. That made me pay more attention to the small interface decisions around the AI output.

Built with: React / FastAPI and Python / OpenAI API / Supabase

Implemented MVP with private source. Messages are pasted into the app.

OTHER WORK

Other builds

Smaller ideas I have explored along the way.

SiteSlip / SnapToSheet

I built a receipt-processing prototype for work such as contracting and deliveries. It takes a photo through image checks, AI extraction and a review step, then exports the details to Excel or CSV. It gave me a way to explore the steps between a messy source document and a usable table.

Prototype

Kitchen record-keeping

A Python and Streamlit prototype for organising restaurant records, including invoices, cleaning and temperature checks. I worked on extracting invoice rows and reviewing them before saving them. Here I focused on reviewing and keeping day-to-day kitchen records.

Prototype

AQOON Tutoring OS

A toolkit of structured Claude prompts and supporting data for tutoring intake, learning plans, sessions and parent updates. I explored how AI could help with preparation while keeping a person responsible for reviewing the material. The interface is still unfinished.

Internal prototype

Halgan Map

A community-map idea I explored with Next.js, MapLibre and geographic data in Supabase. I worked on loading places and filtering them by time to learn how location data becomes an interactive map. Adding new map pins is still unfinished.

Work in progress

OTHER WORK

Experiments and coursework

Smaller ideas I have explored along the way.

Football video analysis

A personal experiment combining a pretrained YOLO model, player tracking and a Streamlit interface to explore football footage. I worked with pitch mapping and heatmaps to learn how video can become useful data. The pass estimates are still experimental.

Personal experiment

[View the project](#)

Logistics Agent

An exploration of forecasting, safety stock and reorder points in Python, with an optional AI step for suggesting adjustments within set limits. It connects ideas from my degree with code. The project is incomplete, but it gave me a concrete way to work through those calculations.

Learning experiment

Road-accident data mining

Coursework comparing classification models on UK road-accident severity data. I explored class imbalance and how different models handled the rarer, more serious cases. One useful lesson was that a high overall accuracy can still hide poor predictions for the cases that matter most.

Coursework

ABOUT / EXPERIENCE

A little about me.

I'm finishing my bachelor's degree in Purchasing and Logistics Engineering at JAMK, with only my thesis remaining. I enjoy talking to people, understanding what makes their work difficult and trying something that might help.

How I work

I use Codex and Claude Code every day to build and work through code. I work on the screens, data and application logic, then test whether they work as intended. These projects are how I practise turning an idea into something useful and discover what I need to learn next.

AQOON

2026 / Community work and service delivery. I speak with families, help them navigate unfamiliar services and build tools for the enquiries and follow-up around that work.

Witas Agile Experiments Incubator

October to November 2025 / 135-hour internship. I worked on an MVP and tested it with customers. Tatu Tuohimetsä, Project Specialist at Witas, is a recommender for this work.

Customer service and operations

Over five years of customer-facing experience. My experience includes retail, independent kiosk shifts, restaurant work and warehouses in Finland. I also worked in automated fulfilment during my exchange in the Netherlands. These jobs taught me to listen, explain clearly and take responsibility for the work in front of me.

What I'm studying

I'm completing my bachelor's degree in Purchasing and Logistics Engineering at JAMK. Only my thesis remains. During my exchange at HAN in the Netherlands, I studied Data-Driven Decision Making, which helped me connect my interest in operations with data and software.

What I'm looking for

I'm looking for a full-time, entry-level role at a startup in Finland or elsewhere in Europe, and I'm open to remote work. Customer success, implementation and operations interest me because they combine helping people with figuring out how a product works. I'd like to contribute to a team, learn from experienced people and grow into more responsibility. In the longer term, I hope to lead a startup of my own.
